Sample Solved Problem from DSP Proakis

Problem Statement Given an LTI system with an impulse response $h[n] = (0.8)^n u[n]$, where $u[n]$ is the unit step function, find the system's output when the input is $x[n] = 2 \cos(\pi n/4)$.

Step-by-Step Solution

- 1. Recognize the System and Input** The system is linear and time-invariant (LTI), characterized by $h[n]$. The input is a cosine sequence.
- 2. Express the Input in Complex Exponential Form** Using Euler's formula: $x[n] = 2 \cos(\pi n/4) = \text{Re}\{2 e^{j\pi n/4}\}$
- 3. Find the System's Frequency Response** The Z-transform of $h[n]$: $H(z) = \sum_{n=0}^{\infty} (0.8)^n z^{-n} = \frac{1}{1 - 0.8 z^{-1}}$, $|z| > 0.8$. Evaluate on the unit circle ($z = e^{j\omega}$): $H(e^{j\omega}) = \frac{1}{1 - 0.8 e^{-j\omega}}$
- 4. Compute $H(e^{j\pi/4})$** Substitute $\omega = \pi/4$: $H(e^{j\pi/4}) = \frac{1}{1 - 0.8 e^{-j\pi/4}}$. Calculate numerator and denominator: $e^{-j\pi/4} = \cos(\pi/4) - j \sin(\pi/4) = \frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2}$. Thus: $1 - 0.8 e^{-j\pi/4} = 1 - 0.8 \left(\frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2} \right) = 1 - 0.8 \frac{\sqrt{2}}{2} + j 0.8 \frac{\sqrt{2}}{2}$. Numerical evaluation: $0.8 \frac{\sqrt{2}}{2} \approx 0.8 \times 0.7071 \approx 0.5657$. So: $\text{Real part: } 1 - 0.5657 = 0.4343$, $\text{Imaginary part: } 0.5657$. Magnitude: $|D| = \sqrt{(0.4343)^2 + (0.5657)^2} \approx \sqrt{0.1886 + 0.3200} \approx \sqrt{0.5086} \approx 0.713$. Phase: $\angle D = \arctan \left(\frac{0.5657}{0.4343} \right) \approx \arctan(1.304) \approx 52.5^\circ$. Therefore: $H(e^{j\pi/4}) = \frac{1}{D} = \frac{1}{|D|} e^{j\angle D} = \frac{1}{0.713} e^{j 52.5^\circ} = 1.4 e^{-j 52.5^\circ}$
- 5. Find the System Output in Frequency**

DomainThe output's frequency component:
$$Y(\omega) = H(e^{j\omega})X(\omega)$$
Since:
$$X(\omega) = 2\pi \delta(\omega - \frac{\pi}{4}) + 2\pi \delta(\omega + \frac{\pi}{4})$$
The relevant component:
$$Y(\pi/4) = H(e^{j\pi/4}) \times 2$$
Similarly, the negative frequency component:
$$Y(-\pi/4) = H(e^{-j\pi/4}) \times 2$$
But because the input is real, the output is the sum of these conjugate components.

6. Final Time-Domain OutputThe output is:
$$y[n] = \text{Re} \left\{ 2 H(e^{j\pi/4}) e^{j\pi n/4} \right\}$$
Using the calculated $H(e^{j\pi/4})$:
$$|H| = 1.4, \angle H = -52.5^\circ$$
Thus:
$$y[n] = 2 \times 1.4 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right) \approx 2.8 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right)$$

Typical Structure of a DSP Proakis Solved Problem

Most solved problems in Proakis' texts follow a structured approach:

- Problem Statement:** Clearly defines the DSP challenge, often involving signal analysis, filter design, or system response calculations.
- Given Data:** Includes parameters such as signal frequencies, sampling rates, filter coefficients, etc.
- Required Solution:** Specifies what needs to be calculated or demonstrated?e.g., system response, filter characteristics, or spectral analysis.
- Step-by-Step Solution:** Breaks down the problem into manageable parts, applying relevant DSP principles, mathematical tools, and algorithms.
- Final Answer and Interpretation:** Presents the solution with explanations, highlighting the significance of the results.

This structured methodology not only facilitates learning but also embodies best practices for tackling complex engineering problems.

Analyzing a Typical DSP Proakis Solved Problem: Case Study

To illustrate, let's analyze a representative problem often encountered in Proakis' texts: Designing a Bandpass Filter Using the Fourier Transform.

Problem Overview: Given a discrete-time signal with a specific spectral content, design a bandpass filter that isolates a frequency band of interest. Calculate the filter's frequency response and verify its effectiveness through simulation.

Step 1: Understanding the Signal and System Requirements

- Signal characteristics:** For example, a sampled signal containing components at 500 Hz and 1500 Hz.
- Sampling frequency:** 4000 Hz.
- Objective:** Filter out the 1500 Hz component, retaining the 500 Hz frequency.

Step 2: Determine Filter Specifications

- Passband:** 450 Hz to 550 Hz.
- Stopband:** Frequencies outside this range.
- Transition band:** Defined based on practical constraints.
- Filter type:** Finite Impulse Response (FIR) or Infinite Impulse Response (IIR).

Step 3: Selecting Filter Design Method

Proakis discusses several methods—windowing, Parks-McClellan algorithm, etc. For simplicity, assume the use of the windowing method: Choose an ideal bandpass filter's impulse response. Apply a window function (e.g., Hamming, Hann) to obtain a realizable FIR filter.

Step 4: Calculating Filter Coefficients

Compute ideal impulse response $h_d[n]$ via inverse Fourier transform. Apply window $w[n]$: $h[n] = h_d[n] \times w[n]$.

Step 5: Analyzing Frequency Response

Use the Discrete Fourier Transform (DFT) or the Fast Fourier Transform (FFT) to evaluate the filter's frequency response $H(e^{j\omega})$. Verify that the passband is adequately preserved and the stopband attenuation meets specifications.

Step 6: Simulating and Validating

Generate a test signal containing multiple frequency components. Pass it through the designed filter. Analyze the output to confirm suppression of unwanted frequencies.

Final Remarks: This problem encapsulates core DSP concepts: filter design, Fourier analysis, system response, and simulation. It demonstrates how theoretical principles translate into practical filter implementation.
