Detailed Breakdown of the June 2013 Questions and Answers

Below, we analyze some of the core questions from the June 2013 paper, offering detailed explanations and insights into the correct solutions.

Question 1: Atomic Structure and Isotopic Composition

Question: A sample of an element contains two isotopes, A and B. The relative atomic masses are 20.00 u and 22.00 u, respectively. The abundance of isotope A is 80%. Calculate the relative atomic mass of the element.

Answer: The relative atomic mass (A_r) is calculated using the weighted average:

$$A_r = (\text{fraction of A} \times \text{mass of A}) + (\text{fraction of B} \times \text{mass of B})$$

$$A_r = (0.80 \times 20.00) + (0.20 \times 22.00) = 16.00 + 4.40 = 20.40 \text{ u}$$

Analysis: This question tests understanding of isotopic abundance and its impact on atomic mass calculations. It underscores the importance of weighted averages in atomic mass determinations, a fundamental concept underpinning modern atomic theory.

Question 2: Bonding and Structure

Question: Describe the bonding in magnesium oxide (MgO). Explain how the bonding influences its physical properties, such as melting point and solubility.

Answer: Magnesium oxide (MgO) exhibits ionic bonding. Magnesium atoms lose two electrons to form Mg^{2+} ions, while oxygen atoms gain two electrons to form O^{2-} ions. These ions are held together by strong electrostatic attractions, forming an ionic lattice.

Influence on Physical Properties:

- High Melting Point:** The strong electrostatic forces between Mg^{2+} and O^{2-} ions require substantial energy to break, resulting in a high melting point ($\sim 2800^\circ\text{C}$).
- Solubility:** MgO is sparingly soluble in water because water molecules can weakly polarize the ions, but the ionic lattice is very stable. Its solubility increases slightly with temperature, typical of ionic solids.

Analysis: Understanding ionic bonding helps predict physical properties. The strong lattice energy correlates with high melting points, while solubility depends on the balance between lattice energy and hydration energy.

Question 3: Energetics and Thermodynamics

Question: Given the following data: Enthalpy change of combustion of ethanol, $\Delta H^\circ_{\text{combustion}} = -1367$

kJ/mol Enthalpy change of formation of ethanol, $\Delta H_f^\circ = -277 \text{ kJ/mol}$ Calculate the enthalpy change for the reaction:

$$\text{C}_2\text{H}_4(\text{g}) + \frac{3}{2} \text{O}_2(\text{g}) \rightarrow \text{C}_2\text{H}_5\text{OH}(\text{g})$$

Answer: Using Hess's Law: $\Delta H = \Delta H_{\text{f, products}} - \Delta H_{\text{f, reactants}}$ But since combustion data is given, we use the relation:

$$\text{C}_2\text{H}_4 + \text{O}_2 \rightarrow \text{C}_2\text{H}_4\text{O} \quad \text{(hypothetically, if needed)}$$

Alternatively, recognizing the given data, a more straightforward approach is to understand that the enthalpy of formation of ethanol is directly provided, so: $\Delta H = -277 \text{ kJ/mol}$

Analysis: This problem involves applying Hess's Law and understanding the relationship between combustion and formation enthalpies. It emphasizes the importance of enthalpy cycle calculations in thermodynamics.

Question 4: Kinetics and Reaction Mechanisms

Question: A reaction between iodine (I_2) and propanone (acetone) in the presence of acid is studied. The rate equation is found to be: $\text{Rate} = k[\text{I}_2][\text{Propanone}]$

Explain what this rate equation suggests about the reaction mechanism.

Answer: The rate equation indicates that the reaction is first order with respect to both iodine and propanone. This suggests that the rate-determining step involves one molecule of I_2 and one molecule of propanone reacting simultaneously. The mechanism likely involves a bimolecular slow step where both reactants participate together, possibly forming an intermediate.

Implication: The overall reaction mechanism is consistent with a two-molecular step, perhaps involving the formation of an iodine-propanone complex or an electrophilic attack facilitated by acid.

Analysis: Understanding rate laws helps elucidate reaction mechanisms. A rate law showing first-order dependence on each reactant is indicative of a bimolecular slow step, critical in reaction pathway analysis.

Question 5: Organic Chemistry ? Synthesis and Isomerism

Question: Describe two isomers of butene (C_4H_8). Explain their differences in terms of structure and reactivity.

Answer: Isomers of Butene:

1-Butene ($\text{CH}_2=\text{CHCH}_2\text{CH}_3$): Structure: The double bond is between carbon 1 and 2. Features: Terminal alkene, with the double bond at the end of the chain.

2-Butene ($\text{CH}_3\text{CH}=\text{CHCH}_3$): Structure: The double bond is between carbon 2 and 3. Features: Internal alkene, with the double bond within the chain.

Differences in Reactivity: 1-Butene is more reactive in electrophilic addition reactions because the terminal double bond is less stabilized and more accessible. 2-Butene exists as two stereoisomers (cis- and trans-), which influence physical properties and reactivity. The trans-isomer is generally more stable due to less steric hindrance.

Analysis: Isomerism in alkenes influences their chemical behavior and physical properties. Recognizing structural and stereoisomers is essential in organic synthesis and reactions.

1. Balancing Chemical Equations

Question: Balance the following reaction:
$$\text{C}_3\text{H}_8 + \text{O}_2 \rightarrow \text{CO}_2 + \text{H}_2\text{O}$$

Answer:

Step 1: Count atoms on both sides.

Step 2: Balance carbon atoms: 3 on reactant side, so produce 3 CO_2 molecules.

Step 3: Balance hydrogen atoms: 8 H on reactant side, so produce 4 H_2O molecules.

Step 4: Balance oxygen atoms: Reactant side: O_2 molecules needed = $(3 \times 2) + (4 \times 1) = 6 + 4 = 10$ oxygen atoms. Since each O_2 has 2 oxygen atoms, number of O_2 molecules = $(10/2 = 5)$.

Balanced Equation:
$$\text{C}_3\text{H}_8 + 5\text{O}_2 \rightarrow 3\text{CO}_2 + 4\text{H}_2\text{O}$$

Key Takeaway: Proper atom counting and systematic balancing lead to correct equations, which underpin all subsequent calculations.

2. Calculating the Limiting Reactant

Question: Given 10 g of propane (C_3H_8) and 20 g of oxygen, determine the limiting reactant and the theoretical mass of carbon dioxide produced.

Answer:

Step 1: Convert masses to moles: Molar mass of C_3H_8 : $(3 \times$

$12.01 + 8 \times 1.008 \approx 44.11 \text{ g/mol}$ Moles of propane: $(10 \text{ g} / 44.11 \text{ g/mol}) \approx 0.2267 \text{ mol}$ Molar mass of O_2 : $(2 \times 16.00 = 32.00 \text{ g/mol})$ Moles of oxygen: $(20 \text{ g} / 32.00 \text{ g/mol}) = 0.625 \text{ mol}$ Step 2: Write the balanced equation: $\text{C}_3\text{H}_8 + 5 \text{O}_2 \rightarrow 3 \text{CO}_2 + 4 \text{H}_2\text{O}$ Step 3: Determine oxygen needed for 0.2267 mol of propane: $0.2267 \text{ mol} \times 5 = 1.1335 \text{ mol}$ Step 4: Compare available oxygen (0.625 mol) to required (1.1335 mol). Since $0.625 \text{ mol} < 1.1335 \text{ mol}$, oxygen is the limiting reactant. Step 5: Calculate CO_2 produced from limiting reactant: $0.125 \text{ mol propane} \rightarrow 3 \times 0.2267 = 0.6801 \text{ mol CO}_2$ Mass of CO_2 : $0.6801 \text{ mol} \times 44.01 \text{ g/mol} \approx 29.92 \text{ g}$ Conclusion: Oxygen limits the reaction, and approximately 29.92 grams of CO_2 can be produced.

How do you determine the molecular formula from the empirical formula and molar mass?

Calculate the molar mass of the empirical formula, then divide the molecular weight by the empirical formula weight to find the multiplier. Multiply the empirical formula subscripts by this multiplier to get the molecular formula.

What is the formula for calculating percentage composition?

Percentage of an element = (Mass of element in compound / Molar mass of compound) $\times$ 100.

How is the ideal gas law formula expressed?

$PV = nRT$, where P = pressure, V = volume, n = number of moles, R = gas constant, T = temperature in Kelvin.

What is the formula for calculating boiling point elevation?

$\Delta T_b = i \times K_b \times m$, where ΔT_b is the boiling point elevation, i is the van 't Hoff factor, K_b is the ebullioscopic constant, and m is molality.

How do you compute the rate constant from reaction data?

Using the rate law expression $\text{rate} = k [\text{reactants}]^n$, rearranged to find $k = \text{rate} / [\text{reactants}]^n$, based on experimental data.

What is the formula for calculating the oxidation number?

Oxidation number rules vary, but generally, for a simple ion, it's equal to its charge; for molecules, assign electrons based on electronegativity differences, following standard rules.

How do you find the equivalent weight of an acid or base?

Equivalent weight = Molar mass / number of hydrogen ions (H⁺) or hydroxide ions (OH⁻) replaced per molecule in a reaction.
